The Clinical Case for Smoking Cessation for WOUND CARE

What is this initiative aiming to achieve?

The aim of this initiative is to provide clinical support for temporary abstinence with a view to prompting a permanent quit supported by a referral to local NHS Stop Smoking Services. To gain maximum benefit, hospital associated abstinence needs to lead to permanent quitting. However, temporary abstinence beginning immediately around the time of admission and lasting until a patient has healed may still have worthwhile benefits.

What is the relationship between smoking and wound healing?

Compared to non-smokers, smokers are more likely to experience complications in tissue healing such as infections and dehiscence. Smoking is also associated with an increased rate of non-union and slowed healing of bone. Smoking has effects on the cardiovascular and respiratory systems, which have the net effect of reducing the amount of oxygen available to the tissues. Oxygen is necessary for wound and bone healing so a smoking induced reduction in oxygen availability is likely to play a major role in wound healing complications.

What are the health benefits of quitting for patients?

Successful quitting will not only benefit a patient’s long term health by reducing the risk of disease development but there is evidence that quitting smoking may reduce wound healing complications (see below).

Main acute effects of smoking on the body (estimated time of recovery, if known)

- Increase in sympathetic tone leading to increase in blood pressure, heart rate and peripheral vasoconstriction leading to an increased demand for oxygen and cardiac function (24-48 hrs)
- Formation of carboxyhaemoglobin leading to reduction in oxygen delivery to the tissues (8-24 hrs)
- Formation of carboxymyoglobin leading to reduction in oxygen storage in the muscles (8-24hrs)
- Increase in red cell production which leads to increase in blood viscosity, a decrease tissue perfusion and decrease in oxygen delivery to the tissues
- Hypersecretion of mucus, narrowing of the small airways, decrease in ciliary function and change in mucus rheology leading to a decrease in mucociliary transport (12-72 hours)
- Changes in functioning of a range of immune cells (pro- and anti-inflammatory cytokines, white blood cells, immunoglobulins) which lead to decreased immunity (1week-2 months)
- Induction of hepatic enzymes which increases drug metabolism through both pharmacokinetic and pharmacodynamic mechanisms (6-8 weeks)

Why intervene in secondary care?

Hospitalisation offers an opportune time to encourage patients to stop smoking for four main reasons.

- Firstly, this time is often a "teachable moment" where patients are more receptive to intervention and are more motivated to quit.
- Secondly, the hospital smokefree environment creates an external force to support abstinence.
- Thirdly, patients are ideally placed to be given information about treatment options, support through withdrawal and signposted to specialist services.
- Fourthly, abstaining from smoking at this time can lead to significant health benefits.
**Improvements in wound healing associated with smoking cessation**

- Reduced rate of wound infections.\(^7,^8\)
- Reduced rate of impaired wound healing.\(^14,^15\)
- Increased rate of bone healing.\(^16,^17\)
- Permanent smoking cessation reduces the risk of heart disease, stroke, cancer and premature death.\(^1\)

**How was this information sheet put together?**

This information is a summary of the current scientific evidence on the association between cigarette smoking and respiratory diseases. Studies were found by searching MEDLINE and EMBASE using combined exploded subject headings of “pneumonia, bacterial, “respiratory tract infections” “respiratory tract diseases” and “tobacco use cessation” from 01/1990 – 10/2009 and by searching the Report of the US surgeon general on the health benefits of smoking cessation.\(^19\) Evidence has been included in this summary from cohort studies, randomised controlled trials and reviews only.

**The 3A’s**

**How to approach smoking cessation with patients**

Smoking cessation interventions have been proven effective for hospitalised patients regardless of admitting diagnosis\(^2\) and specifically for respiratory patients.\(^6\)

NICE guidance has recommended that smoking cessation interventions should be offered to patients with stable COPD, and health professionals are encouraged to offer pharmacological support and refer patients to local NHS Stop Smoking Services.

The DH guidance, “Smoking Cessation in Secondary Care”,\(^9\) is designed to be practical for busy healthcare professionals and outlines a care pathway for supporting smoking cessation that can be adopted for respiratory patients. In essence, the care pathway incorporates a very brief intervention using the 3A’s:

- **ASK** and record smoking status
- **ADVISE** the patient of the personal health benefits of quitting
- **ACT** on the patient response -prescribe NRT for patients in withdrawal -monitor withdrawal and adjust pharmacotherapy accordingly -refer to local NHS Stop Smoking Service
