

## From Airborne exposure to Biological Effects (FABLE)

### Pathways for health impacts of nanoparticles

The unique properties of engineered nanoparticles are highly beneficial to numerous industrial applications, and their use has become widespread. However, little is known about airborne levels in the environment, and their effects on human health.

In the FABLE project at The University of Birmingham, we are taking an interdisciplinary approach to increase understanding of the human health impact of three metal nanoparticles, Cerium, Vanadium and Zinc.

The work entails measurement of levels of nanoparticle oxides of Cerium, Vanadium, Zinc in the ambient environment and modelling personal exposures. These airborne species are characterised and synthesised at Birmingham University in their various physico-chemical forms, to study their potential for

effects in man following uptake via the lungs.

This work includes study of the extent of respiratory uptake, definition of how these particles penetrate various human epithelia, and investigation of their intracellular effects, and association with local and systemic toxic responses. This work makes a major contribution to assessment of risks incurred by beneficial use of these metal nanoparticles, and to this end, we interact with policy makers and industry.
