Angiotensin Converting Enzyme inhibitor (ACEi) / Angiotensin Receptor Blocker (ARB) – To STOP OR Not in Advanced Renal Disease

ROYAL COLLEGE of PHYSICIANS of EDINBURGH

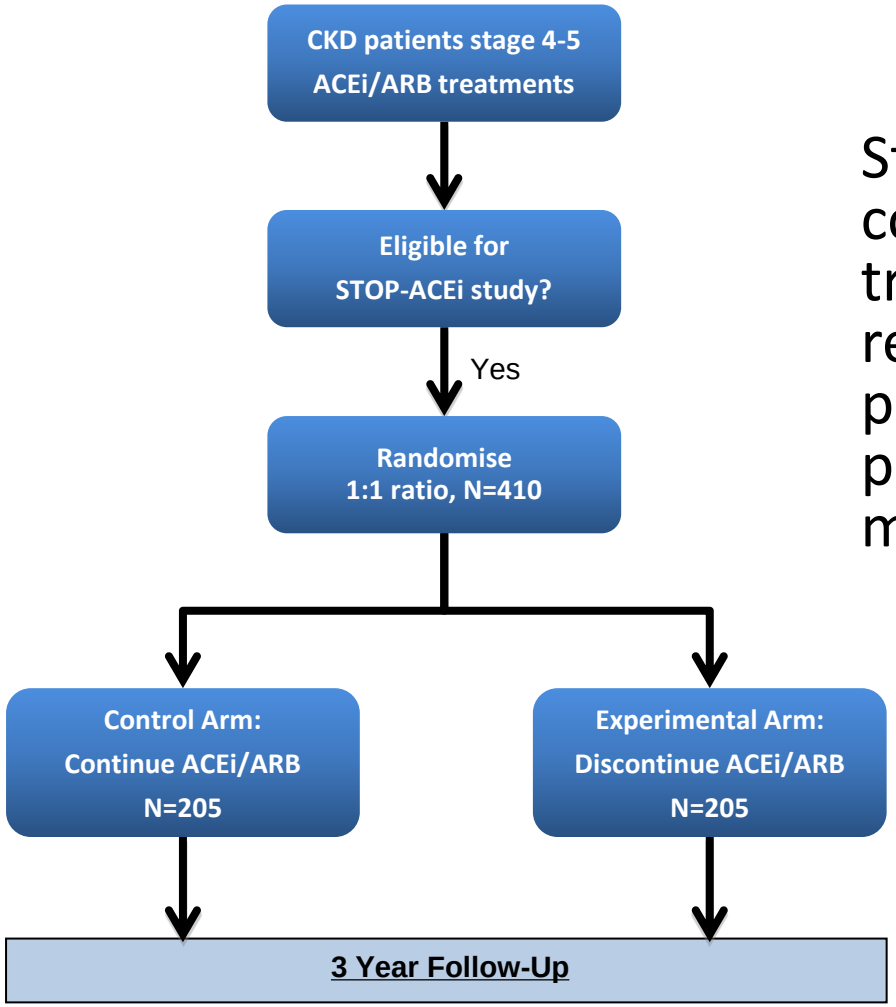
Investigator Meeting

12th September 2017 - Sheffield

Prof Sunil Bhandari
Consultant Nephrologist
Honorary Clinical Professor
International Director RCPE

UNIVERSITY OF BIRMINGHAM | BCTU Birmingham Clinical Trials Unit | Hull and East Yorkshire Hospitals NHS Trust | NHS

Multi-centre Randomised Controlled Trial of Angiotensin Converting Enzyme inhibitor/Angiotensin Receptor Blocker withdrawal in advanced renal disease



Stopping ACEi or ARB treatment, compared with continuing on these treatments, improves or stabilises renal function in patients with progressive stages G4 or G5 CKD provided "good" BP control is maintained

MRC Medical Research Council

NHS National Institute for Health Research

Efficacy and Mechanism Evaluation Programme

Eligibility

Key Inclusion Criteria	Key exclusion criteria
• Aged ≥18 years (male or female) • CKD stage G4 –G5 (MDRD eGFR <30ml/min) & not on dialysis • Progressive deterioration in renal function (fall in eGFR of >2ml/min/year) • Treatment with an ACEi or ARB or a combination of both for >6 months with at least 25% of the maximum recommended daily dose • Resting BP ≤160/90 mmHg • At least 3 months specialist renal follow-up at the time of entry into the trial	• Aged <18 years • Undergoing dialysis therapy • Uncontrolled hypertension (>160/90mmHg) or requirement for 5 or more agents to control BP • History of MI or stroke in preceding 3 months • Pregnancy or breastfeeding • Immune mediated renal disease requiring disease specific therapy

Pre- specified Minimisation Variables

- **Diabetes Mellitus**: Type 1; Type 2; none
- **Blood pressure**: MAP <100; ≥ 100 . [(diastolic x2 + systolic)/3]
- **Age**: <65; ≥ 65 years
- **Proteinuria**: PCR <100 ; ≥100 mg/mmol
- **eGFR**: <15 ≥ 15 ml/min

End-points

410 patients with eGFR <30ml/min and >2ml/min/year loss of eGFR over I year – 3 measures and BP ≤160/90 mmHg and on ACEi/ARB for at least 3 months

ACEi/ARB	STOP- ACEi

Primary Endpoint = 5ml difference at 3 years in eGFR based on MDRD (effect size 0.31 with 80% power and alpha =0.05)

BP	Hospitalisation rates	Urine PCR
RRT/>50% decline	6 minutes walk test	Hb concentration
Time to reach ESRD/RRT	Cardiac events	Change in ESA use
Cystatin C	Survival	
	KD QOL

Guidelines recommend use of RAAS inhibitors for Heart Failure

Class I recommendation

- ACE inhibitors are recommended for patients with asymptomatic LV systolic dysfunction with or without a history of MI in order to prevent or delay the onset of HF and prolong life

Class II recommendation

- ACE inhibitors should be considered in patients with stable coronary artery disease even if they do not have LV systolic dysfunction, in order to prevent or delay the onset of HF

EUROPEAN SOCIETY OF CARDIOLOGY®

ACE=angiotensin-converting enzyme; HF=heart failure; LV=left ventricular; MI=myocardial infarction; RAAS=renin–angiotensin–aldosterone system

Levey AS et al, Kidney Intern 2011;80-17-28

HF studies provide little information to direct care in advanced CKD - patients with significant renal dysfunction were excluded

Table 1. Heart failure trials with baseline renal function

Trial (reference)	Intervention	Cohort	Sample	Follow-up	Creatinine/ eGFR	Outcome
CONSENSUS [46]	Enalapril vs. placebo	NYHA IV HF	253	188 days	124–132 µm/l	Improved symptoms and life expectancy vs. placebo, no impact on sudden cardiac death
Val-HeFT [43]	Valsartan vs. placebo	NYHA I–II HF	5,010	27 months	58 ml/min	Reduced composite mortality and morbidity and improved symptoms
V-HeFT-II [45]	Enalapril vs. hydralazine/ isosorbide dinitrate	Men; NYHA class II–III HF	804	2.5 years	Not measured	Sudden death 14%; mortality from progressive HF 12 vs. 23%
SOLVD-treatment [44]	Enalapril vs. placebo	NYHA class II/III HF and EF <35%	2,569	41 months	1.2 mg/dl (106 µmol/l)	Sixteen percent fewer deaths in enalapril group ($p = 0.0036$), 26% less hospitalizations ($p < 0.0001$)
SOLVD-prevention [42]	Enalapril vs. placebo	Asymptomatic patients with EF ≤35%	4,228	37 months	1.2 mg/dl (106 µmol/l)	Eight percent lower mortality (NS); fewer deaths and hospitalizations due to HF ($p < 0.001$)
CHARM-added trial [38]	Candesartan vs. placebo	LV dysfunction already taking ACEi	2,548	42 months	Not measured excluded >3.0 mg/dl (265 µmol/l)	Candesartan significantly improved all-cause mortality
CHARM alternative [37]	Candesartan vs. placebo	LV dysfunction intolerant to ACEi	2,028	42 months	Nil Excluded >3.0 mg/dl (265 µmol/l)	Candesartan significantly improved all-cause mortality
ELITE I [39]	Losartan vs. captopril	>65 years with HF NYHA II–IV; EF <40%	722	48 weeks	106 µmol/l	No difference in outcomes of worsening renal function
ELITE II [40]	Losartan vs. captopril	>60 years with HF NYHA II–IV; EF <40%	3,152	555 days	Nil	No difference in all-cause mortality 1.13 (0.95–1.35)
ATLAS [41]	Lisinopril vs. losartan	LV dysfunction	3,163	~4 years	1.3 mg/dl (117 µmol/l)	Reduced mortality 8% NS Combined death and hospitalisation 15%

Ahmed/Jorna/Bhandari DOI: Nephron 10.1159/000447068

Reducing Cardiac Outcomes

Does the potential gain of eGFR with ACEi/ARB cessation lead to improved morbidity & mortality or an increase in adverse cardiovascular outcomes?

Cardiovascular guidelines have recommended caution with the use of ACEi/ARBs for patients with HF and advanced CKD

McMurray JJ et al; ESC Committee for Practice Guidelines: ESC guidelines for the diagnosis and treatment of acute and chronic heart failure : European society of Cardiology. Developed in collaboration with the heart failure association (HFA) of the ESC. Eur Heart J 2012; 14: 1787–1847

Guidelines recommend use of RAAS inhibitors for CKD

NICE

Offer a low-cost RAAS antagonist to people with CKD and:[1]

- Diabetes and ACR of ≥3mg/mmol
- Hypertension and ACR of ≥30mg/mmol
- ACR of ≥70mg/mmol (irrespective of hypertension or CVD)

Level 1 recommendation[2]

- We recommend ARB or ACE inhibitor use in both diabetic & non-diabetic adults with CKD & urine albumin excretion >300mg/24 hours (or equivalent)

Level 2 recommendation[2]

- We suggest ARB or ACE inhibitor use in diabetic adults with CKD and urine albumin excretion 30–300mg/24 hours (or equivalent)

ACE=angiotensin-converting enzyme; ACR=albumin:creatinine ratio; ARB=angiotensin II receptor blocker; CKD=chronic kidney disease; NICE=National Institute for Health and Care Excellence; RAAS=renin–angiotensin–aldosterone system

What are the risks and benefits of temporarily discontinuing medications to prevent acute kidney injury? A systematic review and meta-analysis

Summary Headline

Low-quality evidence that withdrawal of ACEI/ARBs prior to coronary angiography & cardiac surgery may reduce the incidence of AKI.

No evidence of the impact of drug cessation interventions on AKI incidence during intercurrent illness in primary or secondary care.

Impact of AKI in terms of the development of CKD or reductions in baseline GFR was not reported.

UK NICE guidance 2013 recommends consideration of temporarily stopping ACEI and ARBs in adults having iodinated contrast agents if they have CKD, eGFR <40 mL/min, and in adults, children and young people with diarrhoea, vomiting or sepsis.

Sick-Day Rules cards, advising to stop taking ACEIs/ARBs, NSAIDS, diuretics and metformin when they become unwell with vomiting or diarrhoea, and/or fevers sweats and shaking.

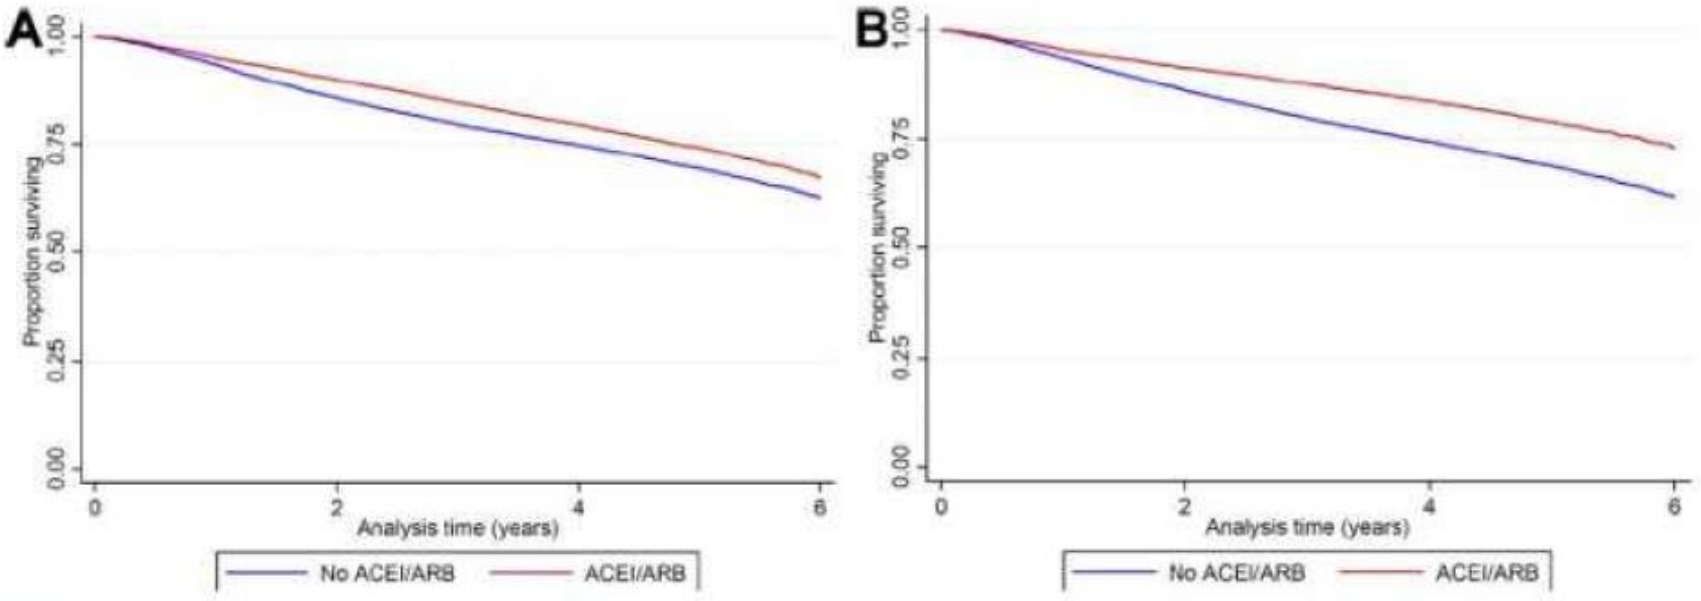
JACC

Angiotensin Converting Enzyme Inhibitor, Angiotensin Receptor Blocker Use, and Mortality in Patients With Chronic Kidney Disease

Figure 1: survival probability of treated and untreated patients in the propensity score matched cohort, with ACEI/ARB treatment -association with lower mortality in both intention to treat and as treated models.



Miklos Z. Molnar; Kamyar KalantarZadeh et al J Am Coll Cardiol. 2014;63(7):650658.

SUMMARY OF FINDINGS

Angiotensin Converting Enzyme Inhibitor, Angiotensin Receptor Blocker Use, and Mortality in Patients With Chronic Kidney Disease

- Administration of ACEI/ARB was associated with lower all cause mortality and a substantial survival benefit in non dialysis dependent patients with CKD even with adjustment for confounders and propensity matching

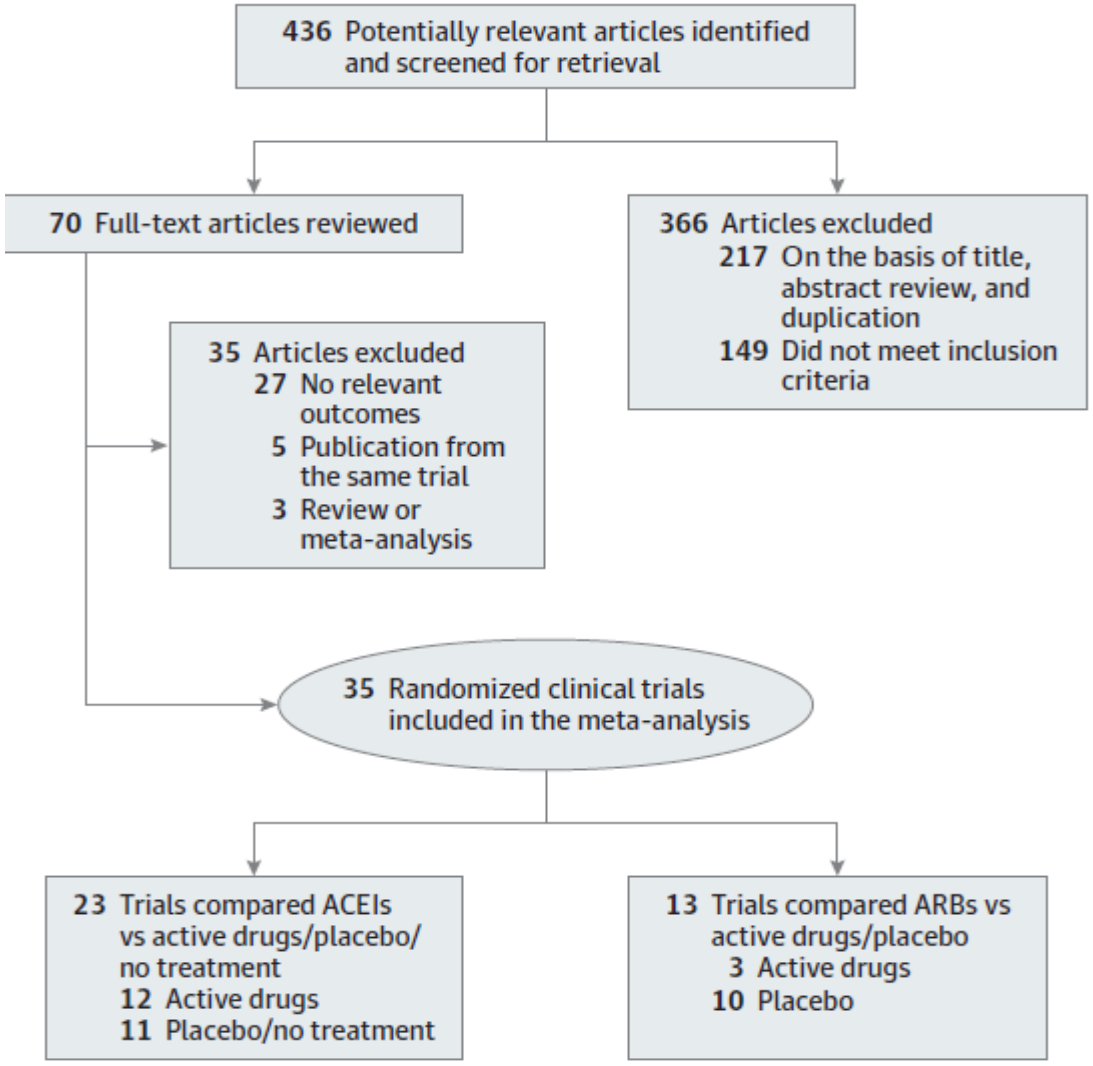
- Non dialysis dependent patients with CKD, discontinuation rates of ACEI/ARB were high:
  - only 66% of treated patients received renewed prescriptions on >50% of their follow up visits
  - only <10% of patients remained on ACEI/ARB therapy throughout all follow up visits

- Patients treated with ACEI/ARB were more likely to be black, have diabetes, hypertension, congestive heart failure, CVD, and higher systolic and diastolic blood pressures

Miklos Z. Molnar; Kamyar KalantarZadeh et al J Am Coll Cardiol. 2014;63(7):650658.

JACC

Effect of Angiotensin-Converting Enzyme Inhibitors and Angiotensin II Receptor Blockers on All-Cause Mortality, Cardiovascular Deaths, and Cardiovascular Events in Patients With Diabetes Mellitus A Meta-analysis



Cardioprotective effects of RAAS blockade were recently called into question.

The NIDDM, Hypertension, Microalbuminuria or Proteinuria, Cardiovascular Events, and Ramipril (DIABHYCAR) study found ACEIs had no effect on CV events in patients with type 2 DM and albuminuria.

There was a higher rate of fatal CV events with olmesartan therapy in ROADMAP (Randomized Olmesartan & Diabetes II Microalbuminuria Prevention)

Cheng et al JAMA Internal Medicine May 2014 Volume 174, Number 5

Summary of effects of ACEi and ARBs on All-Cause Mortality, Cardiovascular Deaths, and Cardiovascular Events in Patients With DM

- ACEIs significantly reduced the risk of:
  - all-cause mortality by ~ 13%
  - CV deaths by ~ 17%.
  - major CV events by 14%
    - myocardial infarction by 21%
    - heart failure by 19%

- ARB treatment did not significantly affect
  - all-cause mortality
  - CV death.
- ARB treatment reduced the risk of
  - heart failure by 30%
